Aim: Declare a class circle with radius as its member. Declare a class paint with rate per square units as its member. A class dish inherits from both classes circle and paint. It has method cost which is cost of painting circular dish on both surfaces. Use parameterized constructors.

Code:

```
#include <iostream>
```

```
class circle
```

```
{  
    public:  
        float radius,area;  
        circle() {}  
};
```

```
class paint
```

```
{  
    public:  
        float rate;  
        paint() {}  
};
```

```
class dish: public circle, public paint
```

```
{  
    public:  
        dish(float radius,float rate)  
    {  
        area=3.14*radius*radius;
```

```
        std::cout<<" The cost of painting the plate is "<<2*area*rate<<" Rs"<<std::endl;
    }
};

int main()
{
    dish d(2,4);
    return 0;
}
```

Output:

The cost of painting the plate is 100.48 Rs
