

Aarya Arban

S11-07

Aim: Implement arithmetic operations in Haskell

Assignment – 6(A)

Aim: Calculate Cost price when selling price and loss is given.

Code:

```
calculateCostPrice :: Double -> Double -> Double
calculateCostPrice sp loss = sp + loss

main :: IO ()
main = do
    putStrLn "Enter the selling price: "
    spStr <- getLine
    let sp = read spStr :: Double

    putStrLn "Enter the loss: "
    lossStr <- getLine
    let loss = read lossStr :: Double

    let costPrice = calculateCostPrice sp loss

    putStrLn ("The cost price is: " ++ show costPrice)
```

Output:

Enter the selling price:

190

Enter the loss:

20

The cost price is: 120.0

Assignment – 6(B)

Aim: Calculate Area of rectangle when length and breadth is given.

Code:

```
calculateArea :: Float -> Float -> Float
calculateArea length breadth = length * breadth

main :: IO ()
main = do
    putStrLn "Enter the length of the rectangle: "
    lengthStr <- getLine
    putStrLn "Enter the breadth of the rectangle: "
    breadthStr <- getLine

    let length = read lengthStr :: Float
        breadth = read breadthStr :: Float

    let area = calculateArea length breadth
    putStrLn $ "The area of the rectangle is: " ++ show area
```

Output:

Enter the length of the rectangle:

2

Enter the breadth of the rectangle:

4

The area of the rectangle is: 8.0
